Abstract

Executive synthesis. CDFL is the command language of the CDFD Runtime. It lets a user define systems, assign domains, run simulations, observe metrics, and trigger rules without writing Python directly. This paper explains the compiler path and the CLI contract that now makes CDFL reproducible through `cdfd.py cdf1 validate`, `cdfd.py cdf1 lint`, `cdfd.py cdf1 format`, `cdfd.py cdf1 ast`, `cdfd.py cdf1 sample`, execution, diagnostics, and JSON export.

Greek-symbol convention. Unless a manuscript states a tighter equation-local meaning, Greek symbols are local CDFD variables or coefficients, not universal constants. Here Φ denotes driving flux, Ψ_s denotes the adaptive operating ratio, Ω denotes a domain or state space, and Λ denotes the Life Number where used. The coefficients α , β , and γ denote accumulation or reinforcement, relaxation or decay, and diffusion, coupling, or re-distribution. The symbols δ and ϵ denote perturbation or tolerance scales, while η , λ , μ , ν , ρ , σ , τ , and ϕ denote local efficiency, rate, baseline, frequency, density or correlation, noise or variance, time-scale, and phase or field terms. Subscripts restrict any coefficient to the named pathway, tissue, domain, or experiment.

Runtime evidence path

Prior CDFD mathematics $\longrightarrow$ CDFL/runtime state $\longrightarrow$ bounded output $\longrightarrow$ falsification target.

Figure 1: Conceptual schematic for the runtime papers. The engine translates the mathematical frame from the prior CDFD papers into executable CDFL/runtime diagnostics; candidate outputs remain tied to explicit tests before any stronger claim is made.

1 Prior CDFD Basis

This manuscript does not rederive the mathematical core of CDFD. It uses the Mujjabi Adaptive Operating Ratio and the constrained-vacuum notation introduced in Part I [1],

the torus-knot hierarchy and boundary-mode work from the Part I sequence [2, 3], the public balance law developed in the Part I capstone [4], the Part I transport tests [5], and the Life Number and tri-regime biology bridge from Part II [6]. The runtime papers therefore act as an execution layer: they keep the mathematics connected to commands, outputs, falsification tests, and domain-specific limits.

2 Why a Language Is Needed

Directly manipulating NumPy arrays is powerful but fragile. A scientific runtime needs a stable way to describe a model, run it, and save the output so that the same model can be reviewed by another reader. CDFL provides that grammar.

3 Compiler Pipeline

3.1 Tokenization

`dsl/lexer.py` and `dsl/tokens.py` convert source text into tokens. The language recognizes keywords such as `SET`, `SYSTEM`, `RULE`, `RUN`, `OBSERVE`, and `PATIENT`. Hash comments are ignored by the lexer, which aligns the runtime with the editor configuration and keeps annotated model files executable.

3.2 Parsing

`dsl/parser.py` converts tokens into AST nodes. A `SystemNode` stores the relation between a named system, a flow expression, and a constraint expression. A `RuleNode` stores threshold logic.

3.3 Execution

`dsl/executor.py` walks the AST. It resolves available variables, computes $\Psi_s = (\Phi/C)SM_s$, routes actions through the dry-run action gateway, and invokes the kernel for `RUN Engine` blocks.

4 Minimal Example

The active example is `examples/heat_flow.cdf1`:

```
SET domain: physics
```

```
SYSTEM HeatChannel {
  flux: 1.2
  constraint: 0.9
  state: psi
}
```

```
RULE HeatOverload {
  IF psi > 1.1
```

```

    ACTION reduce_flux
}

RUN Engine {
    duration: 0.05
    dt: 0.01
}

OBSERVE {
    metrics: [psi]
}

```

This model can be checked and run with:

```

python cdfd.py cdf1 lint examples/heat_flow.cdf1
python cdfd.py cdf1 format examples/heat_flow.cdf1
python cdfd.py cdf1 ast examples/heat_flow.cdf1 --json
python cdfd.py validate examples/heat_flow.cdf1
python cdfd.py run examples/heat_flow.cdf1 \
    --out outputs/heat_flow_run.json

```

5 Language Workbench

The runtime now exposes a CDFL workbench as strict result envelopes rather than only as editor-side convenience:

- **cdf1 lint**: shared diagnostics for malformed statements, block/list balance, rule syntax, and key-value shape;
- **cdf1 format**: deterministic indentation over blocks and lists;
- **cdf1 ast**: a JSON-safe summary of parser nodes and attributes;
- **cdf1 sample**: the canonical heat-flow model for tutorials, tests, and editor smoke checks.

These commands are intentionally modest. They make CDFL reviewable and repeatable while preserving the parser and executor as the source of semantic truth.

6 Editor Surface

The repository now includes `tools/cdf1-vscode`, the Vura Labs *CDFL Language Support* extension. It provides `.cdf1` file association, TextMate highlighting, snippets, local diagnostics, completions, hover help, document symbols, formatting, and command-palette actions that call the same `cdfd.py cdf1` runtime commands. The extension is a research ergonomics layer, not a second compiler.

7 Output Semantics

CDFL execution produces structured result blocks:

- **system**: computed Φ , C , and Ψ_s for named systems;
- **rule**: triggered actions and dry-run gateway output;
- **run**: kernel time series;
- **observe**: requested metrics.

The CLI wraps these blocks in a runtime result envelope with provenance and a finite audit.

8 Connection to Discoveries

The discovery experiments currently use Python scripts, but CDFL is the durable experiment front door. A discovery candidate eventually has:

- a CDFL model file;
- a saved JSON/HDF5 output;
- a report entry;
- a falsification condition;
- a rerun command.

This is how candidate findings move from exploratory notebooks into reproducible runtime claims.

9 Re-Running the Discoveries in CDFL

The final development target remains to rerun more of the selected discovery set from CDFL rather than from ad hoc Python scripts. The short path is not to rewrite every experiment by hand. The current grammar already supports simple parameter and discovery declarations such as:

```
SWEEP pulse_strength [1.0, 2.0, 4.0]
DISCOVER {
  target: vacuum_memory
  output: discovery_vacuum_hysteresis
  falsify: residual_vanishes_under_controls
}
```

The remaining work is to connect richer experiment families, manifests, and HDF5 outputs to these declarations. Once that bridge is complete, selected discoveries can be run through `cdfd.py cdf1 run`, exported as result envelopes, and displayed by VOS or CDFD Runtime Studio without changing the engine mathematics.

10 Limitations

The current CDFL grammar is intentionally small. It does not yet cover every experiment pattern in `experiments/notebooks`. The next development target is to make common sweeps, parameter grids, and discovery runs executable from CDFL manifests without losing Python-level control for advanced experiments.

11 Conclusion

CDFL turns CDFD from a codebase into an executable manuscript language. Its scientific value depends on reproducibility: validate the model, run it, save the output, and make the failure conditions explicit.
